

TES technology can be divided into sensible heat TES, chemical energy storage, and latent heat TES (LHTES) [7]. Sensible heat TES has a low storage capacity and requires a large space for the storage system [8]. Chemical energy storage technology is more complex and requires larger investments [9]. LHTES, on the other hand, uses phase change materials (PCMs), which are ...

Thermal energy storage (TES) is an especially efficient way to effectively reduce the mismatch between demand and supply of energy. To date, thermal energy storage is mainly classified into three types: sensible heat storage [1], latent heat storage [2] and chemical heat storage [3]. Latent heat storage using phase change materials (PCMs) has received much ...

For thermal energy storage applications using phase change materials (PCMs), the power capacity is often limited by the low thermal conductivity (of PCM). Here, a three-dimensional (3D) diamond foam (DF) is proposed by template-directed chemical vapor deposition (CVD) on Cr-modified Cu foam as highly conductive filler for paraffin-based PCM.

However, the relatively low thermal conductivity of phase change materials (PCMs), e.g. paraffin ($\sim 0.2 \text{ W} \cdot \text{m}^{-1} \cdot \text{K}^{-1}$) [23], currently applied to latent heat TES generally limits the energy storage efficiency for the system. It is therefore necessary to enhance heat transfer during phase change process through either increasing effective thermal conductivity ...

Zhu et al. [11] compared the enhancement efficiency of thermal behavior through changing the foam metal porosity, changing the shape of the cold wall, and using the discrete heat sources. By three above optimization methods, the thermal storage efficiency was improved by 83.32% comparing with the pure paraffin. Meng et al. [12] filled copper foam partly on ...

Due to high energy storage capacity, phase change materials (PCMs) are used widely to store thermal energy. But the poor thermal conductivity limits their usage for thermal transport applications. A promising technique

Among these methods, adding fins and metal foam are two relatively simple and efficient strengthening measures, and their applications in the latent heat thermal energy storage unit (LHTESU) have been intensively studied [11, 12]. This paper presents a study on the effect of pore size on energy absorption characteristics of a PCM-metal foam energy storage system. Different metal foam geometries are generated by using a geometry creation model which considers the metal foam structure as a combination of overlapping spherical pores. The geometry creation model is coupled to an ...

Due to its large latent heat and high energy storage capacity, paraffin as one of the phase change materials (PCMs) has been widely applied in many energy-related applications in recent years. The current applications of paraffin, however, are limited by the low thermal conductivity and the leakage problem. To address these issues, we designed and fabricated ...

Under the same simulated sunlight radiation intensity of 1200 W/m^2 , the photo-thermal energy storage of PRG-CCF/PWS reaches 1234.39 J and was 1.95 times CCF/PWS. The energy storage rate reaches $1.37 \text{ J}\cdot\text{s}^{-1}$. As shown in Fig. 7 e, compared with that of 1st, the η of PRG-CCF/PWS was 90.95 %. After 200 thermal cycles, the η was slightly reduced.

Recently, Pu et al. [45] numerically studied a shell and tube thermal energy storage system with three different configurations of PCM-copper foam composites: single PCM-copper foam, radially multi-layered PCM-copper foam and single PCM with gradient porosity copper foam. It was found that single PCM is more suitable than radial multiple ...

Energy absorbers are a class of products that generally absorb kinetic mechanical energy by compressing or deflecting at a relatively constant stress over an extended distance, and not rebounding. Springs perform a somewhat similar function, but they rebound, hence they are energy storage devices, not energy absorbers.

The porosity of the ceramic foam has a similar effect to the filling height on melting time, total stored energy and energy storage rate. (3) In terms of the outer diameter, the enhancement performance of ceramic foam with a small outer diameter is significant; as the outer diameter increases, the difference in the enhancement gets less remarkable.

Energy storage coefficient could reflect the energy storage rate, with fin-foam hybrid tube taking the lead, followed by metal foam tube, fin tube and bare tube. This is inconsistent with the melting behaviors observed above. Download: Download high-res ...

PCMs are linked to three energy storage methods: sensible heat, latent heat and chemical energy. Among the various kinds of PCMs, latent heat storage has been proved to be an effective means for thermal management due to its high storage capacity and small temperature variation from storage to retrieval [1], [2], [3], [4].
