Why is compressed air storage pressure higher than rated working pressure?

The designed storage pressure of the compressed air in the isobaric compressed air storage device is slightly higher than the rated working pressure of pneumatic cylinder. The reason is that a small pressure drop is inevitable between the storage and end-users. Table 1. Basic parameters used in simulation.

The maximum air storage pressure of the CAES system is 10.0 MPa. During the energy release process, the air pressure in the air storage device is gradually reduced to the axial turbine's rated inlet total pressure (7.0 MPa). The numerical model studied includes four chambers, a full circumference nozzle stators and rotors, as shown in Fig. 3.

The compressed air energy storage (CAES) system experiences decreasing air storage pressure during energy release process. To ensure system stability, maintaining a specific pressure difference between air storage and turbine inlet is necessary. Hence, adopting a judicious air distribution scheme for the turbine is crucial.

Potential Energy Storage Energy can be stored as potential energy Consider a mass, m , elevated to a height, h Its potential energy increase is $E_p = mgh$, where $g = 9.81 \text{ m/s}^2$ is gravitational acceleration Lifting the mass requires an input of work equal to (at least) the energy increase of the mass
